mORe than a camera
The IMAGE1 S™ platform
mORer than a camera – the IMAGE1 S™ platform

Achieving optimal surgical results is the main goal of every operating surgeon. In order to meet this objective, the visualization and display of important and crucial structures during the surgical procedure is of paramount importance.

The rapid development of camera technology in recent years has resulted in a better view of the surgical field and a much wider treatment spectrum. This ultimately leads to better outcomes for patients.

New standards in resolution as well as technologies form the basis of this trend.
1 November 2013
IMAGE1 S™ launch
2D rigid; NIR/ICG; flexible video endoscopes

2 May 2014
FLEX-X® IMAGE1 S™ video uretero-renoscope

3 March 2015
IMAGE1 S D3-LINK™/implementation of 3D capability
TIPCAM®1 S 3D LAP 0°/30°

4 September 2015
IMAGE1 S™ HX/HX-P camera head

5 June 2016
TIPCAM®1 S 3D 4 mm ORL

6 August 2016
DC® camera heads for mediastinoscopy

7 December 2016
VITOM® 3D (exoscope with 4K sensors and 3D display)

8 June 2017
IMAGE1 S™ HX/HX-P FI camera head
PDD in FULL HD

9 October 2017
IMAGE1 S™ 4U-LINK/
IMAGE1 S™ 4U camera head
4K resolution for endoscopy

10 August 2018
IMAGE1 S CONNECT® II
A May 2014
+ Expanded preset functionality
+ New languages
+ Enhanced user guidance

B March 2015
+ Stand-by function for light sources
+ Temporary display of camera head/video endoscope data
+ Increased amount of patient data

C August 2015
+ Image rotation in 3D
+ 2D output for 3D signals
+ SCB communication expanded

D June 2016
+ S-Technologies in 3D
+ Zoom in 3D
+ SCB control for ENDOFLATOR® 40/50 and CO₂ MBI® LED

E November 2016
+ Enhanced menu guidance

F June 2017
+ Patient data in live menu
+ Enhanced privacy settings

G August 2018
+ Integration of new IMAGE1 S CONNECT® II
+ Green color option for ICG fluorescence and integration into the OPAL1® tile

Continuous improvement of hardware

Continuous improvement of software
IMAGE1 S™ – a system that meets all requirements

To meet the greater demands placed on visualization in minimally invasive surgery and to keep step with the growing complexity of such procedures, KARL STORZ launched a unique, modular camera system on the market in 2013: IMAGE1 S™.

This system offers the user maximum flexibility to meet present and future needs.

Benefits of modularity:

1. Needs-based procurement – A specific technology that is required at a particular point in time can be selected from the large number of available technologies.

2. Synergistic effects – all modules have the same control module so that computing power does not need constant and unnecessary adjustment. This eliminates the need to procure peripherals such as monitors, documentation units etc. several times.

3. Gains in efficiency thanks to standardization – all OR rooms have the same technological basis, independent of the surgical discipline and specialty.

4. Future-readiness – whereas stand-alone systems are confined to the technology relevant at a specific point in time, the modularity concept ensures that the platform can be upgraded with new technologies at any time. This leaves room for divergent trends so that the user is never confronted with an either/or option.
Combines all technologies IMAGE1 S™ CONNECT®
Resolution is one of the key factors enabling the identification of fine details in endoscopic images. In this context, the terms 4K or UHD are now commonly used in the consumer sector as well as the medical field.

This development offers 4 times the resolution of existing FULL HD standard systems.

With the IMAGE1 S™ 4U-LINK and the IMAGE1 S™ 4U camera head, the IMAGE1 S™ platform integrates two components that benefit from this system.

The platform architecture eliminates the need to choose between individual technologies and helps select the most appropriate technological solution for a specific procedure.
3D Visualization

One of the greatest challenges in MIS is undoubtedly the difficulty of performing complex maneuvering in three-dimensional space (e.g., suturing, dissecting) as the endoscopic image often lacks the third dimension – i.e. depth.

Studies show that 3D vision increases accuracy and reduces operating times\(^1,2,3\). These effects could be demonstrated for both novices and experienced surgeons\(^3\).

The IMAGE1 S D3-LINK\(^\text{TM}\) enables 3D endoscopes with diameters of 10 mm and 4 mm to be easily integrated into the IMAGE1 S\(^\text{TM}\) platform and thus utilize the benefits offered by 3D visualization\(^4\).

Furthermore, VITOM\(^\text{®}\) 3D offers the possibility of three-dimensional visualization in minimally invasive open surgical procedures. In contrast to an operating microscope, the VITOM\(^\text{®}\) 3D features a high depth of focus, small dimensions and an ergonomic working position. Moreover, the system offers enormous flexibility and allows more observers to view the OR field. Ultra-high resolution sensors also ensure a loss-free zoom.
OPAL1® NIR/ICG

Relevant information and structures (e.g., lymph nodes) are often concealed deep under a layer of tissue or are invisible under white light (e.g., perfusion). Even the highest possible resolution is not able to display these effects.

With the help of illumination with near infrared light, the OPAL1® NIR/ICG technology from KARL STORZ is suitable for multidisciplinary use and allows visualization under the surface of the tissue in laparoscopy and open surgery. The use of indocyanine green (ICG) enables the visualization of anatomical structures up to one centimeter deep. Important information such as, for example, perfusion, the bile duct anatomy or the lymphatic system can be better differentiated and thus displayed much more quickly; in many cases, fluorescence imaging may be the only possibility to display information.
Visualization of the hepatobiliary system

Visualization of the biliary anatomy during laparoscopic cholecystectomy. (Prof. L. Boni, Milan, Italy)

Visualization of the vascular system

NIR/ICG fluorescence imaging presents a clear advantage for perfusion assessment, e.g., in the case of anastomoses.

Perfusion control of the bowel for identification of the resection zone (Dr. Skrovina, Nový Jičín, Czech Republic)

NIR/ICG fluorescence imaging seems to have the potential to drastically lower the rate of anastomotic leakage and thus prevent anastomotic insufficiency\(^5, 6, 7, 8\). By reducing associated morbidity and mortality and subsequent cost savings, NIR/ICG fluorescence imaging could offer enormous benefits for the patient and the healthcare system.
Visualization of the lymphatic system

A further field of application for NIR/ICG fluorescence imaging is the visualization of lymph nodes and lymphatics\(^9\). Especially in oncological surgery, it is important to remove the Sentinel Lymph Nodes (SLN) in order to rule out or treat any possible metastasis. Up until now, the use of technetium, a radioactive substance, has been the gold standard. When injected into the periphery of the tumor, ICG follows the same path as the lymph. With fluorescence imaging, the lymph pathway and the location of SLNs can be visualized in real time, even under tissue layers, in a fast, reliable and cost-effective manner.

Visualization of the sentinel lymph nodes in the case of endometrial/cervical carcinoma
(Dr. R. Wojdat, Herford, Germany)

With the IMAGE1 S™ H3-LINK and IMAGE1 S™ H3 Z-FI camera head, NIR/ICG fluorescence imaging can easily be integrated into the IMAGE1 S™ platform and its benefits thus utilized\(^10\).
Green or Blue – it’s up to you!

The OPAL1® technology for NIR/ICG is now available with a new color option. Choose your preference in the IMAGE1 S™ system before or during surgery.

NIR/ICG imaging in green offers intensive fluorescence with clear delimitation to the surrounding tissue. In addition, you can achieve slight optical brightening of the background.*

NIR/ICG imaging in blue, in comparison, delivers a more balanced presentation of fluorescence, especially in well-perfused areas such as the liver. Here you can avoid possible outshining in areas with high fluorescence intensity.

Comparison of color options using an example from urology (fluorescent lymph node)**

Standard white light, NIR/ICG imaging in blue, NIR/ICG imaging in green*
(Dr. Miguel Ramírez Backhaus, Fundación IVO, Valencia, Spain)

* The SPECTRA A (not for sale in the U.S.) visualization mode is not available with imaging in green.

** The approval status of the fluorescent dye may vary. Please inform yourself about it in your hospital/country.
Hybrid procedures

In modern surgery, the surgical methods used are becoming increasingly complex. These so-called hybrid procedures support surgeons in their work. The simultaneous use of rigid and flexible endoscopes offers great benefits, particularly for operations such as choledocholithiasis as well as gastric, bariatric and colorectal surgery. The acquisition of additional information of the organ to be treated by means of laparoscopic and endoscopic visualization, for example, offers the possibility of pre- and postoperative diagnosis or improved intraoperative management of potential complications (e.g., defining resection boundaries, checking for leakages, correct visualization and identification of the OR site). Conventional systems have major problems in terms of ergonomics, costs and documentation. Consequently, these types of interventions often require the use of two towers. This not only restricts the freedom of movement of all participants in the already confined OR environment, it also contributes to higher costs due to the need to procure both towers. Documentation is also critical as a timely overlap of endoscopic and laparoscopic images with two separate video sources may be important but is difficult to achieve. The modularity of IMAGE1 S™ drastically reduces or eliminates these problems completely.
S-Technologies

In addition to the quantity (amount) of pixels, the quality of the individual pixels is important for the quality of the entire endoscopic image. In this context, KARL STORZ attaches great importance to the correct color display and the best possible sensors. Furthermore, S-Technologies help to overcome the current limitations of endoscopic images.

Structures that are located farther away often appear much darker because light intensity is inversely proportional to the square of the distance from the source. The entire image information for this area is missing. Even increasing the light intensity does not help in this case as this is limited, on the one hand, by the size of the telescope and, on the other hand, it causes overexposed areas in the image. Based on a sophisticated software algorithm, CLARA provides a perfectly illuminated image as it dynamically brightens up dark areas in the background.

Contrast is also an extremely important factor in endoscopic imaging. To offer the user optimal visualization, electronic contrast enhancement has been a standard feature in all standard camera systems for decades. This contrast enhancement, however, is very non-specific and results in enhanced contrast for structures that are already easily identifiable by shifting brightness values. CHROMA, therefore, is focused on enhancing contrast in areas that are difficult to see and therefore ensures better visibility.
As the wish for greater contrast and a more homogenous illumination often coincide, CLARA + CHROMA offers a combination of both these technologies.

SPECTRA* takes individual needs for improved differentiation of strongly vascularized and other interesting areas into consideration. By modulating the green, blue and red channels, these areas can be highlighted. This offers an alternative to the standard white light image.

* not for sale in the U.S.
Future Readiness

The modular design of the IMAGE1 S™ platform offers the customer the possibility of a needs-based procurement. The customer is able to assemble individual components according to the building block principle. If requirements change, further technologies can be modularly integrated with little additional costs and minimal effort. This offers the best possible protection for the original investment. New technologies can be integrated according to the same principle and with the same benefits.
Peripherals

A famous proverb says that a chain is only as strong as its weakest link. In imaging, many components are responsible for a good image. In addition to the more obvious components that influence the imaging chain (telescope, camera head, image processor, monitor), peripheral units also make a significant contribution to the viewing and user experience. In order to achieve the goal of the best possible visualization, technologies and solutions must also be considered here.

Peripherals from KARL STORZ can communicate with the IMAGE1 S™ camera platform which also enables automated control of these units.
Peripherals – POWER LED 300

To achieve clear and sharp images that are rich in detail, powerful lighting is necessary to provide adequate illumination of the cavity. Poor illumination results in dark or grainy images and a deterioration of the image impression. The POWER LED 300 delivers a consistently high light output over its entire service life and thus maintains a high image quality. New developments such as higher resolutions or the miniaturization of telescopes/video endoscopes ensure the need for higher luminance levels. Consequently, the quality of light sources is becoming increasingly important.
Peripherals – S-Pilot®

An ideal imaging chain and sufficient light ensure the best possible display of in-situ conditions. What happens if the in-situ conditions themselves are poor? The use of HF appliances in particular often generate a lot of smoke in the body and thus greatly obscures the image impression. To counteract this, S-PILOT® from KARL STORZ offers an active smoke evacuation system which quickly and efficiently removes suspended particles from the site and thus ensures clear vision. In addition to improving image quality, this system also reduces unpleasant odors in the OR.
Peripherals – ENDOFLATOR® 40/50

To be able to perform minimally invasive surgery, a stable cavity is essential. In many cases, this can only be achieved with the introduction of CO₂. Any changes in the cavity can affect the image impression (especially with regard to image brightness) as a result of altered light requirements or a change in the position of the telescope in relation to the boundaries of the cavity. Among other things, powerful insufflators are required to counteract this effect. In this context, powerful performance involves two factors:

1. High flow rate
2. Rapid control/measurements

With a high flow rate, high gas loss can be quickly counteracted, e.g., smoke or gas evacuation. Fast measurement/control with short measurement intervals ensures that the ENDOFLATOR® 40/50 immediately reacts to any changes in pressure conditions and restores pressure. A stable cavity is thus maintained.

9 Contraindications and official approval for the respective countries/applications should be checked by the physician before use.

10 In addition to camera components, a special light source and special telescopes are required.
It is recommended to check the suitability of the product for the intended procedure prior to use.
